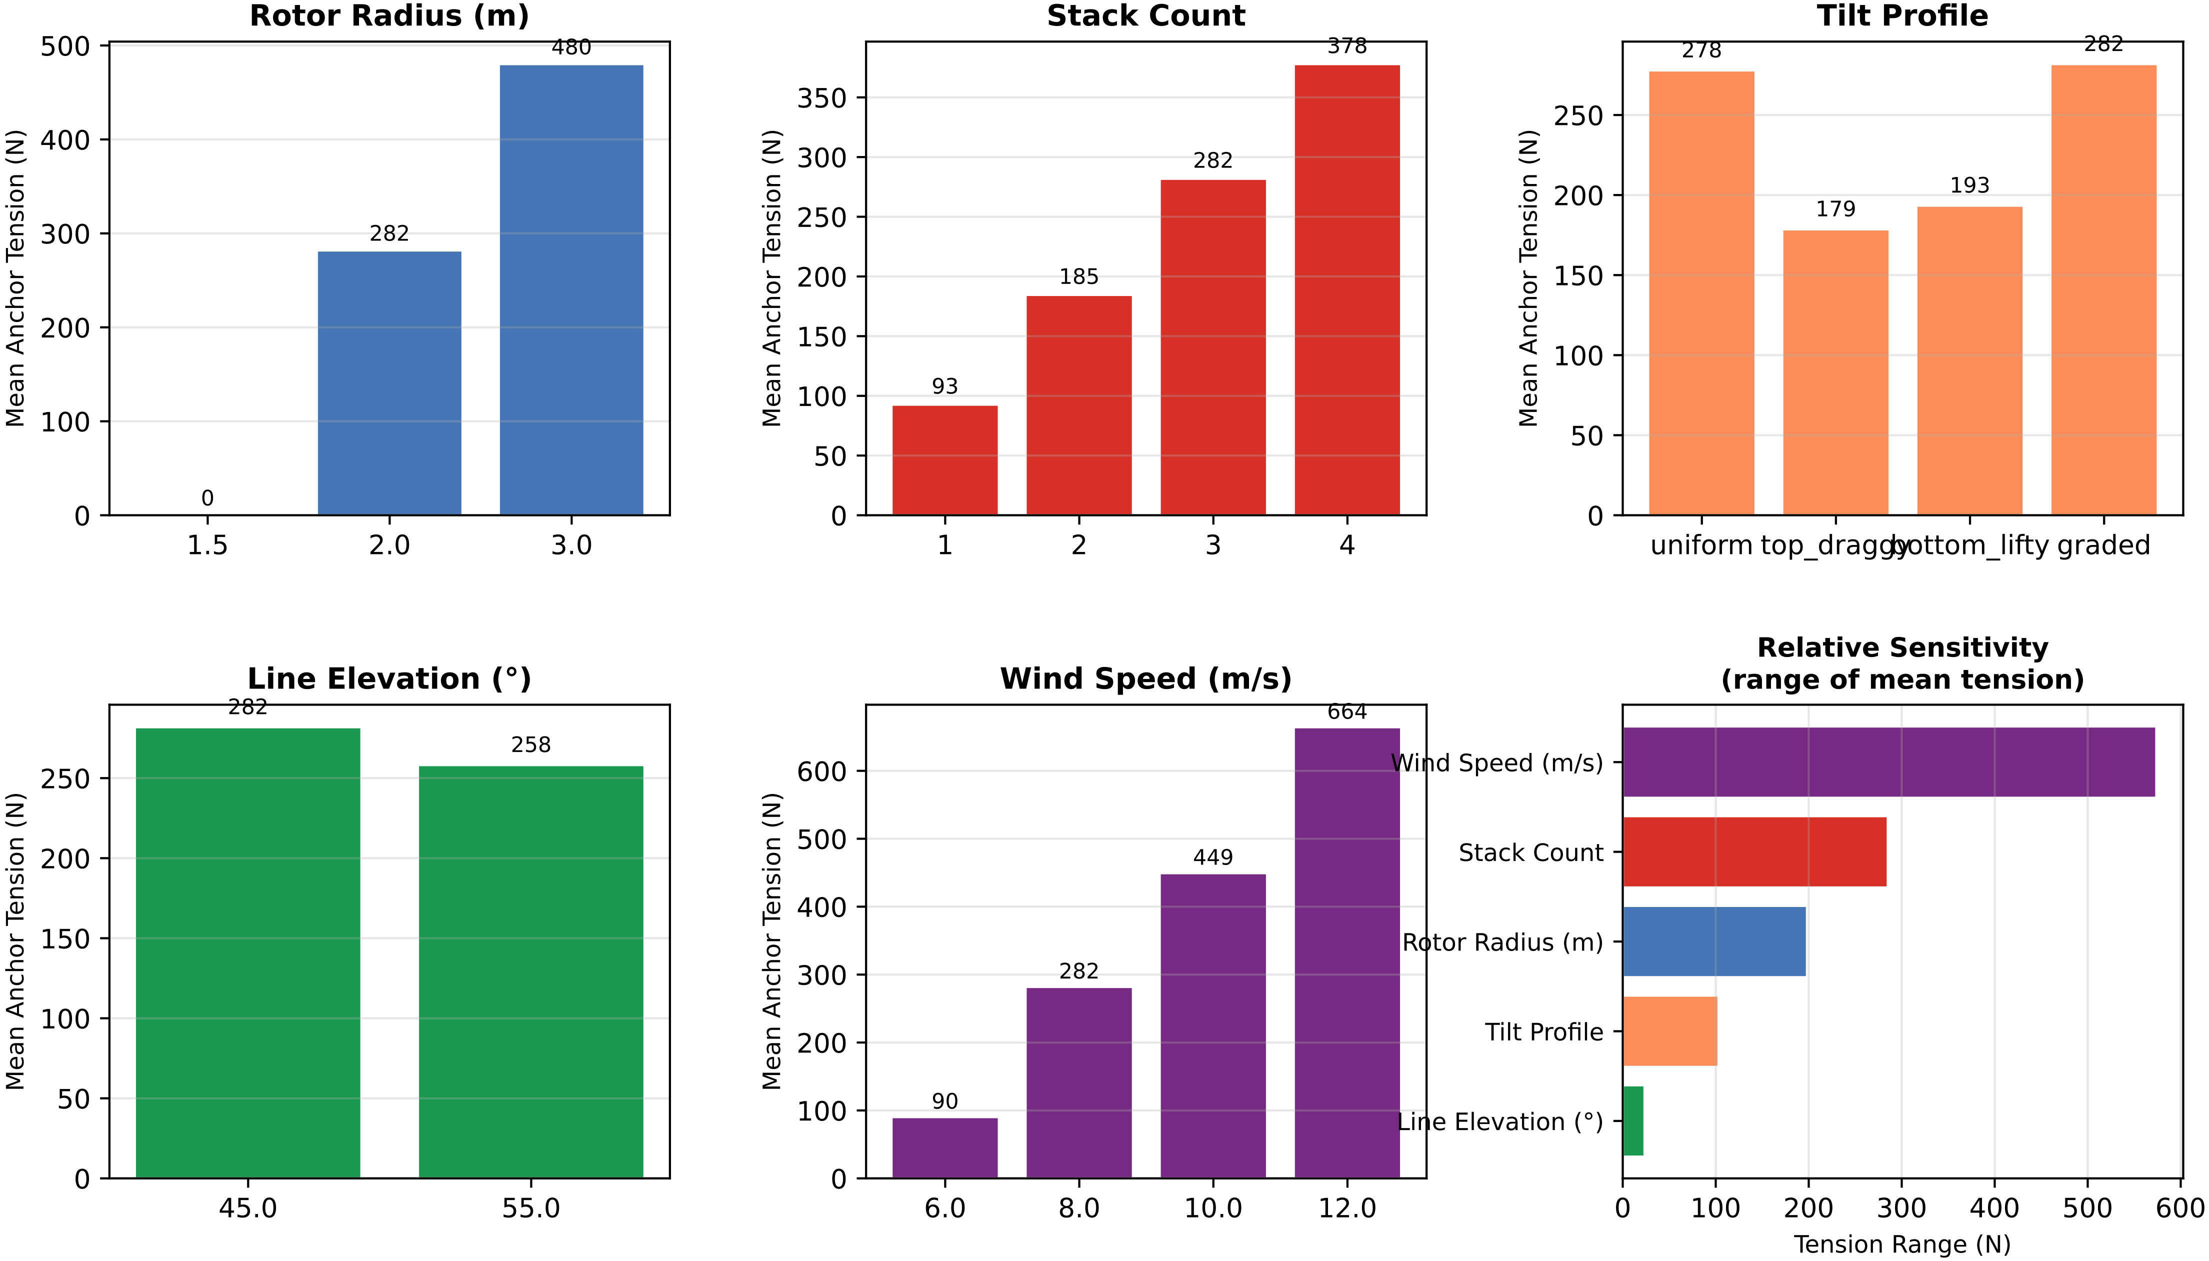
Parameter Sensitivity: Which Design Knob Matters Most?
BEM v2.1 — One-at-a-Time About Baseline Configuration



IMPLICATIONS: Wind speed dominates (tension ∝ v^2). Rotor radius is the strongest design lever — doubling from R=1.5m to R=3.0m increases tension by ~10×. Stack count has diminishing returns: N=1→2 adds more tension than N=3→4. Tilt profile and elevation are secondary effects (<15% variation). Design priority: maximise radius within structural limits, then stack count. Data: BEM v2.1, graded profile baseline, 8 m/s.
