

Cost per Newton: Economics of Scale

BEM v2.1 — Estimated Manufacturing Cost Model

IMPLICATIONS: Cost per newton improves with both rotor radius and stack count — N=4 at R=3.0m achieves \$9.44/N, the best in this sweep. Single rotors (N=1) have the worst cost efficiency at every radius. N=2 is the threshold where larger rotors become cheaper per newton. The cost model is simplified — real costs depend on manufacturing volume, material choices, and labour. Data: BEM v2.1, graded profile, 4-12 m/s.
