

Power Density: TRPT per Swept Area

Power Density by Configuration

TRPT Power Density vs Wind Speed (BEM v2.1, 45° Elevation)

BEM v2.1 — Benchmark Against Wind Turbines (at 8 m/s)

IMPLICATIONS: Power density is 2-5 W/m² at 8 m/s for viable configurations — comparable to small wind turbines. Large wind turbines achieve ~10 W/m² at rated speed because their swept area intercepts the full wind column. The autogyro stack sweeps a smaller effective area (rotor disks, not the full frontal area). R=3.0m, N=4 delivers the highest power density at 3.7 W/m². Data: BEM v2.1, TRPT = tension × wind speed.
