

Tension Accumulation — R=3.0m, N=4, graded, 45°

IMPLICATIONS: Tension accumulates toward the anchor — each rotor adds ~1,250 N of along-line force at 8 m/s (~5,200 N at 16 m/s). Between rotors, bare-line drag adds further tension. Tension above the topmost rotor drops to zero. Note: wind gradient is NOT modeled — all rotors see the same freestream speed. With real wind shear (exponent 0.14), the top rotor at 60m sees ~28% faster wind than at 15m, making upper steps larger. Anchor line must be rated for ~20 kN at 16 m/s for this 4-rotor stack. Data: BEM v2.0, corrected polygon solver. See SPEC.md §6.6.
